LECTURE 1: interpolation, integration, spectral methods

Motivations

exact func. $f(x)$ described by ∞ number of points

how handle approximately (but accurately) in computer, using least cost (bytes)?

- Interpolation:

given exact data $f(x_i)$ at some x_i , model $f(x)$ at other points x
cheap but accurate look-up table for expensive $f(x)$

Contrast: fit noisy data = learning (pdf for) params in model, via likelihood/prior

- (Numerical) integration:

eg computing expectation values given a pdf, or their quantum version

Contrast: Monte Carlo (random, high-dim.) integration, Thurs am

- Differentiation:

get gradient ∇f : for optimization, or get matrix which approx. an ODE/PDE

- Spectral (often Fourier) methods:

If $f(x)$ is smooth, handle very accurately without much extra cost

Deterministic (non-random) methods.

Integr/diff crucial for numerical ODEs and PDEs

Goals for LECTURE I

TODO

teach range of practical methods focusing on 1D
pointers to dimensions $d > 1$

Concepts:

convergence order how does your accuracy improve vs number of discretization points

global (one expansion formula for the whole domain)

vs local (different expansions for x in different regions)

spectral method global, often use FFT, converge faster than any fixed order

adaptivity automatically placing degrees of freedom only where they need to be

rounding error & catastrophic cancellation

interpolation = func. representation, is key to all else

Interpolation in 1D ($d = 1$)

Say $y_j = f(x_j)$ known at nodes $\{x_j\}$

exact data, not noisy

want interpolant $\tilde{f}(x)$, s.t. $\tilde{f}(x_j) = y_j$

N -pt "grid"

Interpolation in 1D ($d = 1$)

Say $y_j = f(x_j)$ known at nodes $\{x_j\}$ N-pt "grid"

exact data, not noisy

want interpolant $\tilde{f}(x)$, s.t. $\tilde{f}(x_j) = y_j$

hopeless w/o assumptions on f , eg smoothness, otherwise...

- extra info helps, eg f periodic, or $f(x) = \text{smooth} \cdot |x|^{-1/2}$

Interpolation in 1D ($d = 1$)

Say $y_j = f(x_j)$ known at nodes $\{x_j\}$ N-pt "grid"

exact data, not noisy

want interpolant $\tilde{f}(x)$, s.t. $\tilde{f}(x_j) = y_j$

hopeless w/o assumptions on f , eg smoothness, otherwise...

- extra info helps, eg f periodic, or $f(x) = \text{smooth} \cdot |x|^{-1/2}$

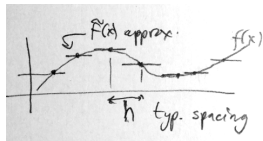

Simplest: use value at x_j nearest to x

"snap to grid"

Error $\max_x |\tilde{f}(x) - f(x)| = \mathcal{O}(h)$ as $h \rightarrow 0$

holds if f' bounded; ie f can be nonsmooth but not crazy

Recall notation " $\mathcal{O}(h)$ ": exists $C, h_0 > 0$ s.t. error $\leq Ch$ for all $h < h_0$

Interpolation in 1D ($d = 1$)

Say $y_j = f(x_j)$ known at nodes $\{x_j\}$ N-pt "grid"

exact data, not noisy

want interpolant $\tilde{f}(x)$, s.t. $\tilde{f}(x_j) = y_j$

hopeless w/o assumptions on f , eg smoothness, otherwise...

- extra info helps, eg f periodic, or $f(x) = \text{smooth} \cdot |x|^{-1/2}$

Simplest: use value at x_j nearest to x

"snap to grid"

Error $\max_x |\tilde{f}(x) - f(x)| = \mathcal{O}(h)$ as $h \rightarrow 0$

holds if f' bounded; ie f can be nonsmooth but not crazy

Recall notation " $\mathcal{O}(h)$ ": exists $C, h_0 > 0$ s.t. error $\leq Ch$ for all $h < h_0$

Piecewise linear:

"connect the dots"

max error = $\mathcal{O}(h^2)$ as $h \rightarrow 0$

needs f'' bounded, ie smoother than before

Message: a higher order method is only higher order if f smooth enough

Interlude: convergence rates

Should know or measure convergence rate of any method you use

- “effort” parameter N eg # grid-points = $1/h^d$ where h = grid spacing, d = dim

We just saw algebraic conv. error = $\mathcal{O}(N^{-p})$, for order $p = 1, 2$

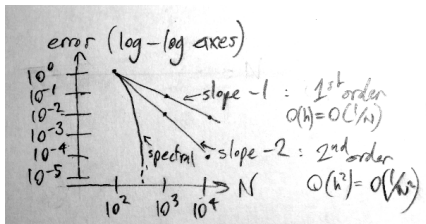

Interlude: convergence rates

Should know or measure convergence rate of any method you use

- “effort” parameter N eg # grid-points = $1/h^d$ where h = grid spacing, d = dim

We just saw algebraic conv. error = $\mathcal{O}(N^{-p})$, for order $p = 1, 2$

Is only one graph in numerical analysis: “relative error vs effort”

Interlude: convergence rates

Should know or measure convergence rate of any method you use

- “effort” parameter N eg # grid-points = $1/h^d$ where h = grid spacing, d = dim

We just saw algebraic conv. error = $\mathcal{O}(N^{-p})$, for order $p = 1, 2$

Is only one graph in numerical analysis: “relative error vs effort”

Interlude: convergence rates

Should know or measure convergence rate of any method you use

- “effort” parameter N eg # grid-points = $1/h^d$ where h = grid spacing, d = dim

We just saw algebraic conv. error = $\mathcal{O}(N^{-p})$, for order $p = 1, 2$

Is only one graph in numerical analysis: “relative error vs effort”

Note how spectral gets many digits for small N

crucial for eg 3D prob.

“spectral” = “superalgebraic”, $\mathcal{O}(N^{-k})$ for any k

- how many digits to you want? for 1-digit (10% error), low order ok, easier to code

<rant> test your code w/ *known exact soln* to check error conv. <\rant>

What is the prefactor C in error $\leq Ch^k$? Has asymp. rate even kicked in yet? :)

Higher-order interpolation for smooth f : the local idea

For any target x , use only set of nearest p nodes:

Exists unique degree- $(p-1)$ poly, $\sum_{k=0}^{p-1} c_k x^k$
which matches local data $(x_j, y_j)_{j=1}^p$

generalizes piecewise lin. idea

do **not** eval poly outside its central region!

- error $\mathcal{O}(h^k)$, ie high order, but \tilde{f} *not* continuous ($\tilde{f} \notin C$) small jumps
if must have cont, recommend splines, eg cubic $p=3$: $\tilde{f} \in C^2$, meaning \tilde{f}'' is cont.

Higher-order interpolation for smooth f : the local idea

For any target x , use only set of nearest p nodes:

Exists unique degree- $(p-1)$ poly, $\sum_{k=0}^{p-1} c_k x^k$
which matches local data $(x_j, y_j)_{j=1}^p$

generalizes piecewise lin. idea

do **not** eval poly outside its central region!

- error $\mathcal{O}(h^k)$, ie high order, but \tilde{f} *not* continuous ($\tilde{f} \notin C$) small jumps
if must have cont, recommend splines, eg cubic $p=3$: $\tilde{f} \in C^2$, meaning \tilde{f}'' is cont.

How to find the degree- $(k-1)$ poly?

- 1) Crafty: solve square lin sys for coeffs $\sum_{k < p} x_j^k c_k = y_j$ $j = 1, \dots, p$
ie $V\mathbf{c} = \mathbf{y}$ $V = \text{"Vandermonde" matrix, is ill-cond. but works}$

- 2) Traditional: barycentric formula $\tilde{f}(x) = \frac{\sum_{j=1}^p \frac{y_j}{x-x_j} w_j}{\sum_{j=1}^p \frac{1}{x-x_j} w_j}$ $w_j = \frac{1}{\prod_{i \neq j} (x_j - x_i)}$
[Tre13, Ch. 5]

Either way, $\tilde{f}(x) = \sum_{j=1}^p y_j \ell_j(x)$ where $\ell_j(x)$ is j th Lagrange basis func:

Global polynomial (Lagrange) interpolation?

Want increase order p . Use *all* data, get single $\tilde{f}(x)$, so $p = N$? “global”
 $p = N = 32$, smooth (analytic) $f(x) = \frac{1}{1+9x^2}$ on $[-1, 1]$: (Runge 1901)

Global polynomial (Lagrange) interpolation?

Want increase order p . Use *all* data, get single $\tilde{f}(x)$, so $p = N$? “global”
 $p = N = 32$, smooth (analytic) $f(x) = \frac{1}{1+9x^2}$ on $[-1, 1]$: (Runge 1901)

- warning: **unif. grid, global interp. fails** → only use locally in central region

Global polynomial (Lagrange) interpolation?

Want increase order p . Use *all* data, get single $\tilde{f}(x)$, so $p = N$? “global”
 $p = N = 32$, smooth (analytic) $f(x) = \frac{1}{1+9x^2}$ on $[-1, 1]$: (Runge 1901)

- warning: **unif. grid, global interp. fails** → only use locally in central region

But exists good choice of nodes...

“Chebyshev”: means non-unif. grid density $\sim \frac{1}{\sqrt{1-x^2}}$

- our first spectral method

$\max \text{err} = \mathcal{O}(\rho^{-N})$ exponential conv!

$\rho > 1$ “radius” of largest ellipse in which f analytic

Node choice and adaptivity

Recap: poly approx. $f(x)$ on $[a, b]$ has good & bad node sets $\{x_j\}_{j=1}^N$

Question: Do you get to *choose* the set of nodes at which f known?

- data fitting applications: No (or noisy variants: kriging, Gaussian processes, etc)
use local poly (central region only!), or something stable (eg splines) [GC12]
- almost all else, interp., quadrature, PDE solvers: Yes so pick good nodes!

Node choice and adaptivity

Recap: poly approx. $f(x)$ on $[a, b]$ has good & bad node sets $\{x_j\}_{j=1}^N$

Question: Do you get to *choose* the set of nodes at which f known?

- data fitting applications: No (or noisy variants: kriging, Gaussian processes, etc)
use local poly (central region only!), or something stable (eg splines) [GC12]
- almost all else, interp., quadrature, PDE solvers: Yes so pick good nodes!

Adaptivity idea

global is inefficient if f smooth in most places, but not everywhere

Node choice and adaptivity

Recap: poly approx. $f(x)$ on $[a, b]$ has good & bad node sets $\{x_j\}_{j=1}^N$

Question: Do you get to *choose* the set of nodes at which f known?

- almost all else, interp., quadrature, PDE solvers: Yes so pick good nodes!

Adaptivity idea

global is inefficient if f smooth in most places, but not everywhere

automatically split
(recursively) panels
until $\max \text{err} \leq \epsilon$

via tests for local error

1D adaptive interpolator codes to try:

- [github/dbstein/function_generator](#) py+numba, fast (Stein '19)
- [chebfun for MATLAB](#) big- p Cheb. grids can exploit FFTs! (Trefethen et al.)

App.: replace nasty expensive $f(x)$ by cheap one!

optimal "look-up table"

Global interpolation of periodic functions I

Just did f on intervals $[a, b]$. global interp. (& integr., etc.) of smooth *periodic* f differs!

Periodic: $f(x + 2\pi) = f(x)$ for all x , $f(x) = \sum_{n \in \mathbb{Z}} \hat{f}_k e^{ikx}$ Fourier series

Global interpolation of periodic functions I

Just did f on intervals $[a, b]$. global interp. (& integr., etc.) of smooth *periodic* f differs!

Periodic: $f(x + 2\pi) = f(x)$ for all x , $f(x) = \sum_{n \in \mathbb{Z}} \hat{f}_k e^{ikx}$ Fourier series

Instead of poly's, use **truncated** series $\tilde{f}(x) = \sum_{|k| < N/2} c_k e^{ikx}$ "trig. poly"

Global interpolation of periodic functions I

Just did f on intervals $[a, b]$. global interp. (& integr., etc.) of smooth *periodic* f differs!

Periodic: $f(x + 2\pi) = f(x)$ for all x , $f(x) = \sum_{n \in \mathbb{Z}} \hat{f}_k e^{ikx}$ Fourier series

Instead of poly's, use **truncated** series $\tilde{f}(x) = \sum_{|k| < N/2} c_k e^{ikx}$ "trig. poly"

What's best you can do?

get N coeffs right $c_k = \hat{f}_k$

error \sim size of tail $\{\hat{f}_k\}_{|k| \geq N/2}$

Global interpolation of periodic functions I

Just did f on intervals $[a, b]$. global interp. (& integr., etc.) of smooth *periodic* f differs!

Periodic: $f(x + 2\pi) = f(x)$ for all x , $f(x) = \sum_{n \in \mathbb{Z}} \hat{f}_k e^{ikx}$ Fourier series

Instead of poly's, use **truncated** series $\tilde{f}(x) = \sum_{|k| < N/2} c_k e^{ikx}$ "trig. poly"

What's best you can do?

get N coeffs right $c_k = \hat{f}_k$

error \sim size of tail $\{\hat{f}_k\}_{|k| \geq N/2}$

How read off c_k from *samples* of f on a grid?

uniform grid best (unlike for poly's!); non-uniform needs linear solve, slow $\mathcal{O}(N^3)$ effort

Uniform grid $x_j = \frac{2\pi j}{N}$, set $c_k = \frac{1}{N} \sum_{j=1}^N e^{ikx_j} f(x_j)$ simply $\mathbf{c} = \text{FFT}[\mathbf{f}]$

Global interpolation of periodic functions I

Just did f on intervals $[a, b]$. global interp. (& integr., etc.) of smooth *periodic* f differs!

Periodic: $f(x + 2\pi) = f(x)$ for all x , $f(x) = \sum_{n \in \mathbb{Z}} \hat{f}_k e^{ikx}$ Fourier series

Instead of poly's, use truncated series $\tilde{f}(x) = \sum_{|k| < N/2} c_k e^{ikx}$ "trig. poly"

What's best you can do?

get N coeffs right $c_k = \hat{f}_k$

error \sim size of tail $\{\hat{f}_k\}_{|k| \geq N/2}$

How read off c_k from *samples* of f on a grid?

uniform grid best (unlike for poly's!); non-uniform needs linear solve, slow $\mathcal{O}(N^3)$ effort

Uniform grid $x_j = \frac{2\pi j}{N}$, set $c_k = \frac{1}{N} \sum_{j=1}^N e^{ikx_j} f(x_j)$ simply $\mathbf{c} = \text{FFT}[\mathbf{f}]$

easy to show $c_k = \dots + \hat{f}_{k-N} + \hat{f}_k + \hat{f}_{k+N} + \hat{f}_{k+2N} + \dots$

$= \hat{f}_k$ desired + $\sum_{m \neq 0} \hat{f}_{k+mN}$ aliasing error, small if tail small

Global interpolation of periodic functions I

Just did f on intervals $[a, b]$. global interp. (& integr., etc.) of smooth *periodic* f differs!

Periodic: $f(x + 2\pi) = f(x)$ for all x , $f(x) = \sum_{n \in \mathbb{Z}} \hat{f}_k e^{ikx}$ Fourier series

Instead of poly's, use **truncated** series $\tilde{f}(x) = \sum_{|k| < N/2} c_k e^{ikx}$ "trig. poly"

What's best you can do?

get N coeffs right $c_k = \hat{f}_k$

error \sim size of tail $\{\hat{f}_k\}_{|k| \geq N/2}$

How read off c_k from *samples* of f on a grid?

uniform grid best (unlike for poly's!); non-uniform needs linear solve, slow $\mathcal{O}(N^3)$ effort

Uniform grid $x_j = \frac{2\pi j}{N}$, set $c_k = \frac{1}{N} \sum_{j=1}^N e^{ikx_j} f(x_j)$ simply $\mathbf{c} = \text{FFT}[\mathbf{f}]$

easy to show $c_k = \dots + \hat{f}_{k-N} + \hat{f}_k + \hat{f}_{k+N} + \hat{f}_{k+2N} + \dots$

$= \hat{f}_k$ desired $+ \sum_{m \neq 0} \hat{f}_{k+mN}$ aliasing error, small if tail small

Summary: given N samples $f(x_j)$, interp. error = truncation + aliasing

a crude bound is $\max_{x \in [0, 2\pi)} |\tilde{f}(x) - f(x)| \leq 2 \sum_{|k| \geq N/2} |\hat{f}_k|$

ie error controlled by mass of tail

Global interpolation of periodic functions II

As grow grid N , how accurate is it? just derived err \sim sum of $|\hat{f}_k|$ in tail $|k| \geq N/2$

Now $\hat{f}_k = \frac{1}{2\pi} \int_0^{2\pi} f(x) e^{-ikx} dx = \frac{1}{2\pi} \int_0^{2\pi} f^{(p)}(x) \frac{e^{-ikx}}{(ik)^p} dx$ integr. by parts p times

So for a periodic $f \in C^p$, recall means first p derivs of f bounded

$$\hat{f}_k = \mathcal{O}(k^{-p}), \text{ tail sum } \mathcal{O}(N^{1-p}) = \mathcal{O}(h^{p-1}) \quad \text{at least } (p-1)\text{th order acc.}$$

Global interpolation of periodic functions II

As grow grid N , how accurate is it? just derived $\text{err} \sim \text{sum of } |\hat{f}_k| \text{ in tail } |k| \geq N/2$

Now $\hat{f}_k = \frac{1}{2\pi} \int_0^{2\pi} f(x) e^{-ikx} dx = \frac{1}{2\pi} \int_0^{2\pi} f^{(p)}(x) \frac{e^{-ikx}}{(ik)^p} dx$ integr. by parts p times

So for a periodic $f \in C^p$, recall means first p derivs of f bounded

$$\hat{f}_k = \mathcal{O}(k^{-p}), \text{ tail sum } \mathcal{O}(N^{1-p}) = \mathcal{O}(h^{p-1}) \quad \text{at least } (p-1)\text{th order acc.}$$

Example of: f smoother \leftrightarrow faster \hat{f}_k tail decay \leftrightarrow faster convergence

Global interpolation of periodic functions II

As grow grid N , how accurate is it? just derived $\text{err} \sim \text{sum of } |\hat{f}_k| \text{ in tail } |k| \geq N/2$

Now $\hat{f}_k = \frac{1}{2\pi} \int_0^{2\pi} f(x) e^{-ikx} dx = \frac{1}{2\pi} \int_0^{2\pi} f^{(p)}(x) \frac{e^{-ikx}}{(ik)^p} dx$ integr. by parts p times

So for a periodic $f \in C^p$, recall means first p derivs of f bounded

$$\hat{f}_k = \mathcal{O}(k^{-p}), \text{ tail sum } \mathcal{O}(N^{1-p}) = \mathcal{O}(h^{p-1}) \quad \text{at least } (p-1)\text{th order acc.}$$

Example of: f smoother \leftrightarrow faster \hat{f}_k tail decay \leftrightarrow faster convergence

Even smoother case: f analytic, so $f(x)$ analytic in some complex strip $|\text{Im } x| \leq \alpha$
then $\hat{f}_k = \mathcal{O}(e^{-\alpha|k|})$, exponential conv in N (fun proof: shift the contour)
as with Bernstein ellipse, to get exp. conv. rate need understand f off its real axis (wild!)

Global interpolation of periodic functions II

As grow grid N , how accurate is it? just derived $\text{err} \sim \text{sum of } |\hat{f}_k| \text{ in tail } |k| \geq N/2$

Now $\hat{f}_k = \frac{1}{2\pi} \int_0^{2\pi} f(x) e^{-ikx} dx = \frac{1}{2\pi} \int_0^{2\pi} f^{(p)}(x) \frac{e^{-ikx}}{(ik)^p} dx$ integr. by parts p times

So for a periodic $f \in C^p$, recall means first p derivs of f bounded

$$\hat{f}_k = \mathcal{O}(k^{-p}), \text{ tail sum } \mathcal{O}(N^{1-p}) = \mathcal{O}(h^{p-1}) \quad \text{at least } (p-1)\text{th order acc.}$$

Example of: f smoother \leftrightarrow faster \hat{f}_k tail decay \leftrightarrow faster convergence

Even smoother case: f analytic, so $f(x)$ analytic in some complex strip $|\text{Im } x| \leq \alpha$
then $\hat{f}_k = \mathcal{O}(e^{-\alpha|k|})$, exponential conv in N (fun proof: shift the contour)
as with Bernstein ellipse, to get exp. conv. rate need understand f off its real axis (wild!)

Smoothest case: “band-limited” f with $\hat{f}_k = 0, |k| > k_{\max}$,
then interpolant exact once $N > 2k_{\max}$

That’s theory. In real life you always **measure** your conv. order/rate!

Take-home: for f smooth & periodic, unif. grid global spectral acc.

- use FFTs, cost $\mathcal{O}(N \log N)$, to go between $f(x_j)$ grid & \hat{f}_k Fourier coeffs

Flavor of interpolation in higher dims $d > 1$

If you *can* choose the nodes:
tensor product of 1D interp.
either global
or adaptively refined boxes

periodic, global

adaptive $p = 6 \times 6$ Cheby

Flavor of interpolation in higher dims $d > 1$

If you *can* choose the nodes:
tensor product of 1D interp.
either global
or adaptively refined boxes

periodic, global

adaptive $p = 6 \times 6$ Cheby

If *cannot* choose the nodes:
interp. $f(\mathbf{x})$ from scattered data
 $\{\mathbf{x}_i\}$ is hard

Eg google terrain: $f(\mathbf{x})$ rough \rightarrow v. low ord,
see amusing transition in interp. type:

Or if know f smooth

fit local multivariate polynomial

If f noisy and smooth, many
methods
kriging, kernels, ***

height $f(\mathbf{x})$
interp from
unstructured
points in 2D,
kernel method

pock-marks!

interp from
Cartesian grid,
more accurate

Numerical integration (back to $d = 1$)

Task: eval. $\int_a^b f(x)dx$ accurately w/ least number of func. evals, N

“quadrature”: nodes $\{x_j\}$, weights $\{w_j\}$ s.t. $\int_a^b f(x)dx \approx \sum_{j=1}^N w_j f(x_j)$

Idea: get interpolant \tilde{f} thru data $f(x_j)$, \rightarrow *integrate that exactly*

Examples:

- local piecewise linear \rightarrow composite trapezoid rule

$w_j = h/2$ at ends, h in middle. low-order: error $\mathcal{O}(N^{-2})$

- global poly \rightarrow Newton–Coates

- can do better: is “Gaussian” node set giving twice this rate!

x_j, w_j codes in scipy, matlab, etc

Periodic case:

periodic spectral get periodic trap rule $\mathcal{O}(c^{-N})$ if analytic

all $w_j = \frac{2\pi}{N}$

PTR exact out to $N - 1$, not merely $N/2$ (detail)

Adaptive panels each with Gaussian

“interpolatory quadrature”

Advanced integration

custom quadratures for singularities, eg $f(x) = \text{smooth} \cdot |x|^{1/2}$ (CCM: ask Manas Rachh)

change of variables (sinh-tanh transform to remove endpoint singularities)

Higher dims: For d up to a few, products of 1D nodes exp. cost $N = n^d$

can also do in other coord sys, eg sphere = $z \in [-1, 1]$ tensor prod. with periodic $\phi \in [0, 2\pi)$

adaptivity works: subdivide boxes

Higher d

Monte Carlo methods: sum N values of $f(\mathbf{x}_j)$ for \mathbf{x}_j random points

error = $\mathcal{O}(N^{-1/2})$ 1/2-order acc, indep of dim d

Note MCMC does not easily give $\int f(\mathbf{x})d\mathbf{x}$, just ratios of such

Numerical differentiation

Goal: given ability to eval. $f(\mathbf{x})$ anywhere, how get $\nabla f(\mathbf{x})$?

obviously again we have to assume f smooth

Finite differencing idea: $f'(x) = \frac{f(x+h)-f(x-h)}{2h} + \mathcal{O}(h^3)$ Taylor's thm

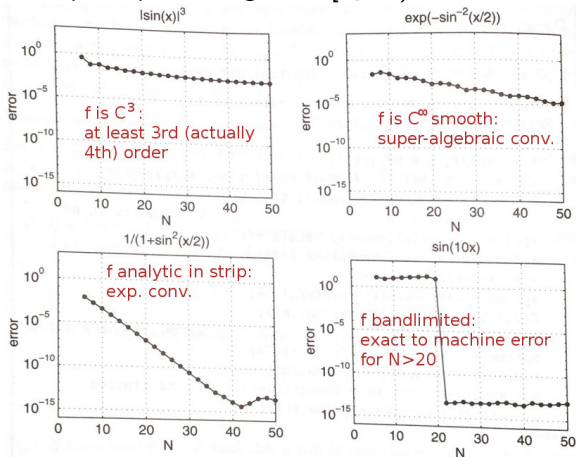

*** demo of error vs h .

trade-off rounding error

Rounding error [GC12, Ch. 5–6] coming in Lec II

Differentiation in $d = 1$

As w/ integration: once have interpolant, differentiate it exactly
 D is $p \times p$ matrix acting on func. values $\{f(x_j)\}$ to give $\{f'(x_j)\}$
Examples: periodic grid in $[0, 2\pi)$, max error:

Recap concepts

repeat list of concepts

LECTURE II: numerical differential equations

GOALS

Reminder of types and applications of diff. eq.

- ODEs: eg pendulum $u''(t) + \sin(u(t)) = 0$ task: solve $u(t)$ efficiently & acc.
needs initial conditions to kick it off eg $u(0) = 1, u'(0) = 0$
eg kinetics of system of well-mixed chemicals, \mathbf{u} is vector
- time-independent PDEs, usually “elliptic” Mike will explain
eg Poisson eqn $\Delta u = g$, $u(\mathbf{x}) =$ chemical concentration or electric potential
 \mathbf{x} means (x, y, \dots) , Δu means Laplacian $\partial^2 u / \partial x^2 + \partial^2 u / \partial y^2 + \dots =$ curvature of u
 $g(\mathbf{x}) =$ volume source of chemical or charge
needs boundary conditions (BCs) on u , or decay at infinity
eg viscous fluid flow: \mathbf{u} is velocity field, Stokes eqns
eg what is ground state of quantum system, solving t-indep. Schrödinger $\Delta u = Eu$?
- time-dependent (evolution) PDEs $u(\mathbf{x}, t)$ varies in space and time
eg heat/diffusion equation $\partial u / \partial t + \Delta u = g$ $g(\mathbf{x}, t) =$ source
needs initial and BCs BCs may vary in time...

[Mike will in next talk overview the three flavors of PDE]

BCs: simple (eg periodic cube) vs complicated ($u = 0$ on a nasty surface)

IVPs to BVPs

Motivate focus on BVPs by mentioning:

- Most people familiar with method of lines
- Equivalent “propagator” approach: discretize time, then solve BVP
- Most timesteppers are FD methods (some examples)

Finite difference methods

Basic viewpoint:

- Construct Taylor-series approximation to value at neighboring points
- For N points, expand to $(N-1)$ derivatives (error $\mathcal{O}(h^N)$)
- Eliminate system to get approximation to d -th derivative ($d < N$) (error $\mathcal{O}(h^{N-d})$)

Alternate viewpoint:

- Differentiate the unique interpolating polynomial of deg $N-1$
- Illustrate with centered forward 1st-order scheme, centered 2nd-order scheme (get extra degree for free).

Timestepping with finite difference methods

Consider temporal ODE $u'(t) = f(u(t))$

Explicit methods: simple, just require evaluating $f(u_n)$.

- E.g. Forward Euler: use 1st-order forward difference rule

Unstable for large timesteps

$$u'(t) = -\lambda u(t) \quad \lambda > 0 \quad (1)$$

$$\frac{u_{n+1} - u_n}{k} = -\lambda u_n \quad (2)$$

$$u_{n+1} = (1 - k\lambda)u_n \quad (3)$$

$$\boxed{k\lambda < 2} \quad (4)$$

Implicit methods: stable, but require solving $f(u^{n+1}) = \dots$

- Backward Euler: use 1st-order backward difference rule

Stability, but potentially at high cost

$$u'(t) = -\lambda u(t) \quad \lambda > 0$$

$$\frac{u_{n+1} - u_n}{k} = -\lambda u_{n+1}$$

Advanced finite difference techniques

- Selecting stencils term by term (e.g. upwinding)
- Adaptive stencil selection (e.g. WENO)

Resources: ...

Codes: ...

Finite element methods

Partition domain into elements, represent unknown within each element using basis functions (usually polynomials)

Convert equations to weak form

- Give example
 - Weak form advantages: lowers order, works if lower derivs are integrable (good for discontinuities, hyperbolic), can use tent functions
- Replace weak form with Galerkin/weighted-residual form to get algebraic system

Traditional FEM methods use tent functions, produce continuous solutions. Fluxes at cell boundaries can be computed from internal representation, but can be discontinuous (non conservative).

Finite volume methods

Case of FEM taking functions to be piecewise constant inside elements
Resulting system is exactly conservative (good for hyperbolic), but requires Riemann solve

- Order increased by using neighbors to reconstruct higher order internal representations or fluxes (slope/flux reconstruction)
- Reconstruction is nonlinear to control oscillations around discontinuities (TVD, ENO/WENO).

Very common in CFD, CCA

Advanced finite element methods

- Discontinuous Galerkin: allow discontinuities, need Riemann solvers again
- Spectral elements: move towards large p for better internal representations

Codes: ...

Spectral methods

Limit of very few elements with very large p : exponential accuracy for smooth problems

Traditional techniques: Fourier spectral methods.

- Fast due to FFT: optimal complexity with exponential accuracy
- Limited to simple geometries / equations with symmetries

Polynomial spectral methods

- More flexible in terms of equations
- Still limited to simple geometries: cubes, spheres, cylinders, etc.
- Still a weak method, but don't integrate by parts. Apply Galerkin directly.

Modern research: sparse methods for arbitrary equations.

Codes: ...

Boundary integral methods

Use knowledge of PDEs in constructing numerical solutions:

A Green's func G (fundamental soln) needed

eg $\Delta G = \delta$

For linear PDEs dominated by boundary rather than bulk terms, compute solution by forming integral equation of the fundamental solution/Green's function. Reduced dimensionality. Improved conditioning. Low-rank interactions and fast methods. Reconstruct solution in the bulk.

Examples: Stokes flow, Helmholtz, Maxwell, typically with homogeneous media

heavily uses high-order integration methods

- see Jun Wang's talk later today!
